Extended Abstract

Background: Data on time use reveal significant insights not only on how people manage time but also of the life circumstances that influence its use. Family structure, labor force participation, and educational attainment are among the factors that are strongly associated with time use. Women, mothers in particular, face enormous challenges with time allocation given the competing demands of family and work. As women get older, shifts in time allocation capture not only life course changes but also health and disability conditions that come with age.

Objectives: This study describes how women allocate their time to different tasks, and the shifts in time allocation that occurs as women age. Individual and household characteristics that influence the use of time are also examined.

Data Source and Methods: This study used data on 2006 non-pregnant women aged 35-68 y from the Cebu Longitudinal Health and Nutrition Survey (CLHNS), a community-based prospective study of ever-pregnant women in Metro Cebu, Philippines. The CLHNS is an ongoing longitudinal study and to date, there are 21 survey rounds since 1983. The data collection was done in the home of the women using structured questionnaires. The amount of time usually spent daily on activities such as food preparation, housekeeping, caregiving, working at home, working away from home, leisure, and sleep was calculated based on the women's 24-hr activity diaries (reported for a typical weekday) completed in 1994, 1998, 2002 and 2005. Characteristics associated with time use were identified using tobit regression models (for censored time use data) and linear regression models. Cluster analysis was run to identify clusters of women grouped by time use patterns. Multinomial logistic regression models were run to identify characteristics associated with each cluster. All analyses were done using STATA 11 (Copyright 1984-2009).

Preliminary findings: As of the recent survey, majority of the women in our study performed food preparation and housekeeping tasks (Table 1). About a third were still involved in caregiving and doing paid work at home. Interesting findings highlight various constraints on women's time and the implications of aging on time use. For example, multivariate tobit models using 2005 data show that the number of househelp and adults in household decrease time spent on food preparation and housekeeping while presence of spouse and children < 7 had the opposite effect (Table 2). Furthermore, increasing age is associated with paid work at home. Women who have more assets and reside in more urban communities tend to work away from home (Table 3). As women age, time spent on caregiving, working away from home, and sleeping significantly decreased while leisure time progressively increased (Figure 1). Using cluster analysis, women were grouped based on their predominant time use patterns for each survey. Four distinct time use groups were identified: working at home, working away,

predominantly doing housework, and some housework with high leisure time. Using these groups in the 4 survey points, longitudinal time use patterns were created (Table 4) showing predominant tasks and shifts in time allocation across surveys. Women in these categories were shown to have significant differences in education, assets and urbanicity.

Summary and Discussion: In 2005 survey, only 5% of the women were more than 59 years old and more than one-third were nearing old age. Although a small percentage of our sample belongs to older ages, the Philippines like many other Asian countries are slowly experiencing population aging. Findings from this study provide valuable insights in understanding the constraints on women's time and the implications of aging on time use. Results support other studies that as women age, more time is spent on recreation¹. Furthermore, with longitudinal data on time use, it would make possible comparisons in time use patterns across time with other Asian studies². Some limitations of our time use data such as under or over reporting of activities and time spent on activity, recall bias for social desirability and "typical activities" may be hard to define.

Table 1. Example of how women allocate time (2005 survey)

Activities	% Performing task	Mean no. Of minutes spent on task	% Time spent on task
Caregiving	39.1	43.0	3.0
Food preparation	73.3	76.7	5.3
Housekeeping	74.7	92.9	6.4
Paid work done at home	27.4	119.2	8.3
Paid work done away from home	42.7	210.9	14.7
Leisure	98.7	345.9	24.0
Sleep	100.0	439.16	30.5

Table 2. Tobit regression coefficients of characteristics associated with household chores (2005 survey)

	Caregiving	Food Preparation	Housekeeping
Age in 2005	-3.42*	0.62	0.93
Assets	-2.22	-1.76	-1.72
Education	1.69	0.23	0.90
Urbanicity	-0.18	-0.44*	0.45
With househelp	-12.75	-33.80*	-103.15*
Spouse in household	27.49*	28.53*	14.92
Children <7	66.43*	-0.47	2.11
Adults in household	-5.84	-3.49*	1.06

* significant at $p < 0.05$

Table 3. Tobit regression coefficients of characteristics associated with paid work (2005 survey)

	WORK AWAY	WORK HOME
Age in 2005	3.41	-5.51*
Assets	34.48*	-19.47*
Education	-23.80*	15.76*
Urbanicity	3.06*	-1.60
With househelp	-113.12	247.40*
Spouse in household	78.82	-107.26*
Children <7	-47.19	-22.16
Adults in household	-10.78	8.38

* significant at $p < 0.05$
